# State, seed, and coordinate origin

Write all three explicitly before comparing attribution maps

**Canonical Endpoint**

$$L^{end} = x \odot \nabla s(x)$$

state: x · seed: x · no baseline forward

**Baseline-relative Endpoint**

$$L^{\Delta end} = \Delta x \odot \nabla s(x)$$

state: x · seed: x − $x_0$

**Integrated Gradients**

$$IG = \Delta x \odot \int_0^1 \nabla s(x_\alpha) d\alpha$$

states: full path · seed: x − $x_0$

Equal maps require the seeds and the evaluated Jacobians to agree—not just the same model name.
