01 | Same endpoint principle; different attribution rules

Original NNS-CNN conditions and the full ViT endpoint graph share input-value seeds.

NNS-CNN endpoint	NNS-ViT Endpoint	Earlier Path-integrated
Conv / ReLU / MaxPool	Patch / LN / attention / MLP	Same ViT; many path states
$J_{s,x}(x)\,\mathrm{diag}(x)$	$J_{s,x}(x)\,\mathrm{diag}(x)$	$\int_0^1 J_{s,x}(x_\alpha)\,d\alpha$
$L_s = x \odot \nabla s(x)$	$L_s = x \odot \nabla s(x)$	$L_s = \Delta x \odot \int_0^1 \nabla s(x_\alpha) d\alpha$
Current gates and winner	Full Q/K/V and residual paths	Seed: displacement from baseline
Paper-formula identity under consistent local-Jacobian rules	Internal-target Gradient x Input One endpoint; no baseline forward	Internal-target Integrated Gradients Input and baseline both specified

Fixed-attention Value-path IG explains a conditional target with clean A held fixed; full Path IG differentiates Q/K/V.

The architecture specifies the Jacobian. The seed and evaluation rule specify endpoint versus path attribution.
