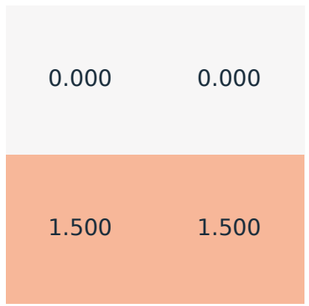
06 | Neuron, channel sum and original filter aggregation

Same h = Px. The target determines the learning image; activation weighting changes the target.

Single unit

$s = h_2 = 3$

Endpoint learning image

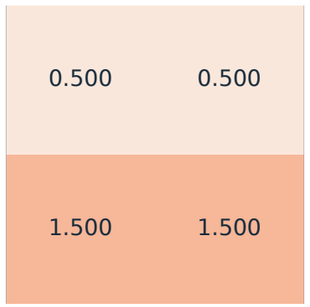


$\Sigma = 3.0000$

Channel sum

$s = h_1 + h_2 = 4$

Endpoint learning image



$\Sigma = 4.0000$

Feature-map energy

$s = (h_1^2 + h_2^2)/2 = 5$

Endpoint learning image

$\Sigma = 10.0000$

$$I^{filter} = \sum_t h_t L_{h_t} = x \odot \nabla_x \left(\frac{1}{2} \sum_t h_t^2 \right)$$

The paper's activation weights and unit maps must refer to the same tensor. Sum and energy are distinct targets.

Energy is planned, not yet registered. In this quadratic example the endpoint sum is 2s = 10, not s = 5.
